**Introduction**

Process liquid analyzers such as pH meters, conductivity meters, ORP meters, and density meters play an important role at electrolysis plants in the control of concentrations of various process solutions. This requires both precision and stability under harsh conditions that include highly corrosive substances, high temperatures, and many impurities.

**Expected Benefits**

- Ensures stable, continuous measurement in heavily contaminated liquids
- Reduces operating costs
- Eliminates the need for manual cleaning

**List of Analyzers**

**Sodium hypochlorite is formed by diluting caustic soda and having it react with chlorine gas. The ISC202 Inductive Conductivity Meter is used here as a concentration analyzer.**

**PH control of desalinated water at the inlet of dechlorination tank is extremely important to keep the dechlorination efficiency in the dechlorination tank. Since the desalinated water contains chlorine gas, the DPA405 pH Electrode, with a special anticorrosive ability and high-viscosity gel for internal electrolysis quality, is used for pH measurement in this tank.**

**The chlorine gas discharged from an electrolysis tank is dehumidified and dried with concentrated sulfuric acid. Control of the concentration of sulfuric acid used for drying is very important in monitoring the drying rate. The sulfuric acid concentration at the drying tower's inlet is 74wt%, and the concentration at the outlet is 98wt%. The ISC202 Inductive Conductivity Meter is used here as a concentration analyzer.**

**Water content in gas at dryer tower inlet: 20°C supersaturated**

**Water content in gas at dryer tower outlet: 0.1 to 0.3 mg/Nl. (126 to 378 vol ppm)**

**Sodium hypochlorite is formed by diluting caustic soda and having it react with chlorine gas. The ISC202 Inductive Conductivity Meter is used to control the reaction conditions, and the ORP meter is used to control the end of the reaction.**

**With IM electrolysis, the NaOH concentration in the electrolyte at the electrolysis tank cathode chamber outlet is 20 to 35%. The water content of this solution is evaporated in the concentrate drum, and the solution is concentrated to 48 to 49% NaOH. The DM8 Vibration Liquid Density Meter is used in concentration control, but the concentration values are displayed on a separately installed computer.**

**Chlorine gas, a byproduct in an electrolysis tank, and hydrogen are burned, forming hydrogen chloride, and this is absorbed in raw water (demineralized water) to form a 35% solution of hydrochloric acid. The ISC202 Inductive Conductivity Meter, whose sensor has superior anticorrosive properties, is used to control the concentration of the product hydrochloric acid.**
Conclusion

Yokogawa process solution analyzers deliver stable, long-term measurements under the harsh conditions present in electrolysis plants. The ISC202 Inductive Conductivity Meter is specially designed to detect the concentrations of hydrochloric acid, sulfuric acid, and caustic soda. The DPA405 pH Electrode for Chemical Processes can measure pH in a wide variety of processes.

Field Data

Each graph shows a correlation between concentration and conductivity at measurement points, the numbers of which correspond to the ones in the previous page. The ISC inductive conductivity meter’s range can be specified, thereby allowing high-resolution measurements in the target concentration range.

The correlation between concentration and conductivity is largely affected by solution temperature. The ISC inductive conductivity meter provides automatic temperature compensation using the built-in temperature sensor.
